AmaliTech-AWS Hackathon Rubrics

Oct 13, 2026

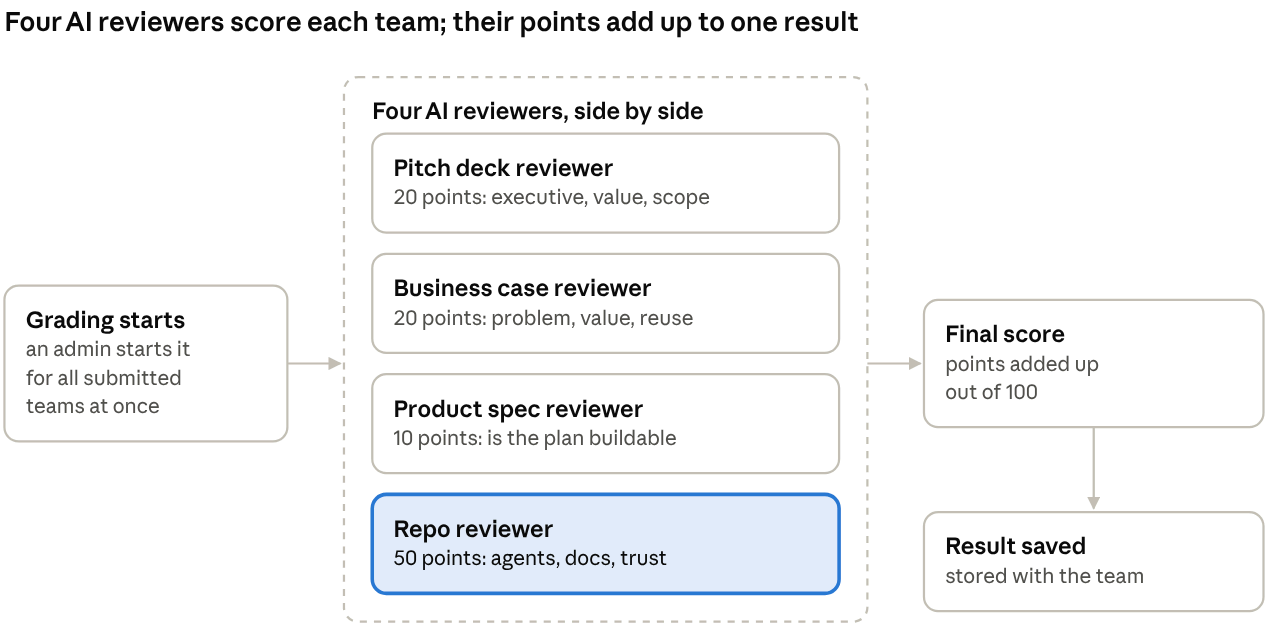

Overview

Every team is scored out of **100 points**. Four AI reviewers each look at a different part of the submission. Their points are added up, and the total decides the outcome. Teams present their demo to the judges on site, so nothing needs to be hosted or sent as a link.

The GitHub repo carries the most weight, **50 of the 100 points**, because the brief rewards how well the agents are designed, documented and trusted more than how the pitch looks. Inside the repo, the markdown files and the agent definitions count most. This event is for problems inside existing companies, so the pitch deck and business case ask about the executive and the value, not about market size or a go-to-market plan.

The AI is set up for consistency, so the same submission should get the same score each time. Every team is graded against the same written criteria.

How a team is graded

evaluation pipeline · 4 agents, 1 aggregator

An admin starts grading for every submitted team in one go. Each team's materials go to four AI reviewers at the same time, and each reviewer scores only its own area. The final score is saved with the team's submission.

What each reviewer looks for

For the three written documents and the repo, the AI rates each item from 0 (missing) to 4 (exceptional). A team gets that share of the item's points. For example, a rating of 3 out of 4 on an 8-point item earns 6 points.

Pitch deck: 20 points

What is judged	Points	What earns them
Named executive	6	A named portfolio-company executive, such as the COO, CFO or VP of operations, whose week gets better. Not the CIO
What it replaces	5	The manual or consultant process it replaces, and what that costs today
Why it is agentic	5	Multiple steps, a decision about what to do next and tools it chooses between. If a Lambda and a SQL query would do the job, it is the wrong brief
Scope and demo moment	4	Cut down to what can be built in two days, with a clear moment where the demo lands

Business case: 20 points

What is judged	Points	What earns them
The problem	8	A real, specific and painful problem for a named role inside a portfolio company
Value if solved	7	The impact sized in real numbers with the assumption stated, such as days saved, margin recovered or cost removed
Reuse across portfolio companies	5	A clear case that it works as a template for the next portfolio company, not only this one

This reviewer is told to reward specifics over polish. Named roles, real numbers and stated assumptions score well, and vague claims score low. If something isn't in the document, the team gets no credit for it.

Product spec: 10 points

What is judged	Points	What earns them
Completeness	3	Clearly states what the product must do
Feasibility	3	The features are realistic to build
Priorities	2	Clear about what gets built first
User stories	1	Describes how real users will use it
Success measures	1	Measurable targets for knowing it works

GitHub repo: 50 points

An AI reviewer reads the team's GitHub repo, laid out as in section 4 of the brief: eight markdown files (README, ARCHITECTURE, AGENTS, EVALS, DEMO, COST, DECISIONS and HANDOFF) and the agents, tools, evals, infra and demo folders. It also checks the history of changes. The markdown files and the agent definitions count most.

What is judged	Points	What earns them
AGENTS.md	10	One row per agent with all seven columns: name, single responsibility, input schema, output schema, tools it may call, guardrail and failure mode. Every row complete
Roles and orchestration	10	One job per agent, nameable in six words. The orchestrator plans and routes and does no domain work, and ARCHITECTURE.md says which steps are fixed Step Functions flows and which are agents
Trust built in	12	Every claim cites a source. A critic judges blind and visibly rejects something. The reject loop is bounded by a counter in the run ledger. Human approval before any write, guardrails on, and a budget ceiling per run
Honest evals	6	EVALS.md records the fixed input set, the real scores and what still fails. A record with no failures counts as missing
README, cost and handoff	8	The README gets someone running in 5 commands and the repo follows the brief's layout. COST.md gives a measured cost per run and at 100 runs a day. HANDOFF.md says what is real, what is faked and what breaks first. DEMO.md and DECISIONS.md are there and useful
Worked examples and tests	4	A real input and its real output committed for each agent, and unit tests on the deterministic tools

The brief's five hard gates apply as well. A repo that fails any one of them fails, whatever its points:

1. It deploys from a clean account with the documented commands.
2. The eval set runs and its results are written down, including the failures. A perfect EVALS.md is treated as a missing one.
3. No autonomous write to any system of record.
4. No real client data anywhere in the repo, the logs or the prompts.
5. AGENTS.md exists and every row is complete.

How the final score adds up

The repo makes up half of the score. The pitch deck and business case together make up 40 points and cover the case for the problem: who wants it, what it replaces and what it is worth.

Area	Points
Pitch deck	20
Business case	20
Product spec	10
GitHub repo	50
Total	**100**
